Abstract. The adult morphology is described and illustrated of *Neoplagioporus kajika* sp. n. (Digenea: Opecoelidae) found in the Japanese fluvial sculpin *Cottus pollux* Günther (Osteichthyes: Scorpaeniformes: Cottidae) collected in the Naka River at Terase Bridge, Narutake, Nakagawa Town, Fukuoka Prefecture, Kyushu, Japan. This new species is characterized by that the body shape is oval, that the intestinal caeca end posteriorly at the middle level of the testicular region, that the ovary is trilobed, and that the vitelline follicles are distributed between the pharyngeal level and usually the posterior end of body and fill up the lateral fields of body. The new species is different from three hitherto known *Neoplagioporus* species, *N. zacconis* (Yamaguti, 1934) Shimazu, 1990 (type species), *N. ayu* (Takahashi, 1928) Shimazu, 1990, and *N. elongatus* (Goto et Ozaki, 1930) Shimazu, 1990, in a combination of these characteristics. The new species is considered mainly infective to *C. pollux* in the river.

The genus *Neoplagioporus* Shimazu, 1990 (Digenea: Opecoelidae: Plagioporinae) consists of three species, *N. zacconis* (Yamaguti, 1934) Shimazu, 1990 (type species), *N. ayu* (Takahashi, 1928) Shimazu, 1990, and *N. elongatus* (Goto et Ozaki, 1930) Shimazu, 1990, which have been known to be parasitic in the intestine of freshwater fishes in Japan and Korea (Takahashi 1928, Goto and Ozaki 1930, Yamaguti 1934, 1938, Shimazu 1990). The specimens taken into account in the species description were obtained from a single female fish 60.3 mm in standard length, collected at Terase Bridge on March 5, 2005. The type series consists of 12 mature specimens of a total of 20 from the fish.

In addition, two specimens were obtained from fishes besides sculpins collected in Sakuta channel at Yamada, which is about 2 km away from Narutake. One mature specimen was found in the intestine of 1 of 58 individuals examined of *Zacco temminckii* (Temminck et Schlegel) (Osteichthyes: Cypriniformes: Cyprinidae). The infected fish was collected on April 23, 2004. One immature specimen was found in 1 of 15 individuals examined of *Pseudogobio esocinus* (Temminck et Schlegel) (Osteichthyes: Cypriniformes: Cyprinidae). The infected fish was collected on March 28, 2004.

Worms were slightly pressed under coverslips and fixed in AFA for one day. They were stained with Heidenhain’s iron haematoxylin, and mounted in Canada balsam. Drawings were made with the aid of a drawing tube. Measurements (length by width) are given in millimetres unless otherwise stated. The type and voucher specimens studied have been deposited in the National Science Museum, Tokyo (NSMT) and the Institute of Parasitology, Academy of Sciences of the Czech Republic, České Budějovice.

**DESCRIPTION**

*Neoplagioporus kajika* sp. n.  --- Fig. 1A–E

**Description.** Based on 12 gravid type specimens. Body oval, not oculate, 1.42–2.08 by 0.59–0.86. Tegument is thin, not corrugated. Body oval, not oculate, 1.42–2.08 by 0.59–0.86.
ment smooth. Oral sucker ventroterminal, 0.19–0.23 by 0.19–0.27. Prepharynx short. Pharynx spherical, 0.08–0.11 by 0.09–0.13. Oesophagus 0.09–0.21, bifurcating at about middle level between pharynx and ventral sucker. Intestinal caeca extending to middle level of testicular region. Ventral sucker just anterior of mid level of body, 0.28–0.38 by 0.27–0.36; sucker width ratio 1:1.17–1.68. Testes entire, oval or elliptical, almost tandem, contiguous, in posterior half of hindbody; anterior testis 0.17–0.39 by 0.20–0.42, posterior 0.17–0.39 by 0.25–0.42. Cirrus pouch claviform, anterior to or slightly overlapping ventral sucker. Seminal vesicle internal, distinctly divided into two portions; posterior portion elliptical or round, anterior elongated. Pars prostatica short, surrounded by prostatic cells. Cirrus short. Genital atrium small. Genital pore sinistral, extracecal, slightly posterior to pharyngeal level. Ovary trilobed, median or dextrosubmedian, usually intercaecal, pretesticular. Seminal receptacle club-shaped, submedian, preovarian or partially overlapping ovary. Laurer’s canal opening dorsally, near left intestinal caecum. Ootype-complex just anterior to ovary, and

**Fig. 1.** *Neoplagioporus kajika* sp. n. from *Cottus pollux*, photograph (A) and line drawings. A, B – entire worm, ventral view (holotype); C – entire worm, ventral view (paratype); D – ovarian complex, ventral view (holotype); E – male terminal genitalia, ventral view (holotype). Scale bars: A–C = 1 mm; D, E = 0.1 mm.
often overlapping seminal receptacle. Mehlis’ gland well developed. Uterus coiled a few times between anterior testis and ventral sucker, intercaecal. Eggs oval, numbering 7–33 per worm, 61–83 by 34–49 µm, one side hollow, the other side sometimes protruding, not fully embryonated when laid. Vitelline follicles distributed along intestinal caeca, anteriorly to pharyngeal level and confluent there, posteriorly to posterior end on both sides of body and confluent there, or to posterior end on left side of body but only to testicular region on right side, or rarely to posterior border of posterior testis on both sides, filling up both lateral fields of body. Excretory vesicle I-shaped, reaching anteriorly to about posterior level of anterior testis. Excretory pore posterterminal.

**Hosts:** Cottus pollux Günther (Osteichthyes: Scardeniiformes: Cottidae) (type host), Zacco temmincki (Temminck et Schlegel) (Osteichthyes: Cypriniformes: Cyprinidae), and Pseudogobio esocinus (Temminck et Schlegel) (Osteichthyes: Cypriniformes: Cyprinidae).

**Site of infection:** Intestine.

**Type locality:** Naka River, Terase Bridge, Narutake, Nakagawa town, Fukuoka Prefecture, Kyushu, Japan (33°32′N, 130°25′E) (March 5, 2005).

**Specimens deposited:** Holotype NSMT-Pl 5445 from C. pollux; 11 paratypes NSMT-PI 5446–5455 and Institute of Parasitology, Academy of Sciences of the Czech Republic, České Budějovice D-591 from C. pollux. Voucher specimens NSMT-Pl 5456 from Z. temmincki and NSMT-Pl 5457 from P. esocinus.

**Etymology:** The specific name “kajika” is the Japanese common name of the type host.

**Remarks.** Following the key given by Cribb (2005), the species here described fits well in the genus Neoplagioporus Shimazu, 1990. Neoplagioporus kajika resembles *N. zacconis*. However, the new species is different from it in having the peripheral lateral fields of body being filled up with the vitelline follicles, while *N. zacconis* has the peripheral fields free from vitelline follicles. Specimens of *N. zacconis* collected from *Z. platypus* (Temminck et Schlegel) captured by us in the Naka River (NSMT 5458–5459) were smaller in body size (based on 15 specimens; 0.44–0.66 in body width) than *N. kajika*. However, Yamaguti’s specimens (1934, 1938) measured by Shimazu (1990) are larger (0.67–1.50 in body width) and almost same size as the new species. Thus, body size is not useful to characterize these two species. The new species is different from *N. elongatus* in having an oval body shape, smaller eggs measuring 61–83 by 34–49 µm instead of 76–96 by 44–60 µm (Shimazu 1990) and 94–110 by 54–68 µm (Shimazu and Urabe 2005), and the vitelline follicles extending anteriorly to the pharyngeal level. The new species is distinguished from *N. ayu* as described by Shimazu (1990) by the length of intestinal caeca to extend posteriorly only to the testicular region of the body instead of to near posterior end of the body, that the testes are located in the posterior half instead of the middle third of the hindbody, that the vitelline follicles are distributed anteriorly to the pharyngeal level instead of the bifurcal, that the Laurer’s canal opens near the left caecum instead of median, and that the excretory vesicle extends to the anterior testis instead of the posterior.

In the present study, specimens of the new species were obtained mainly from *C. pollux*, and rarely from *Z. temmincki* and *P. esocinus*. Specimens of *N. zacconis* (NSMT 5468–5469) were obtained mainly from *Z. platypus* and rarely *Z. temmincki* in the same river. Those of *N. elongatus* (NSMT 5460–5467) were obtained from *P. esocinus*, *Pungtungia herzi* Herzenstein (Cyprinidae) and Coreoperca kawamebari (Temminck et Schlegel) (Percoformes: Siniperidae) in the same river. No specimens of *N. zacconis* or *N. elongatus* were found in *C. pollux*. This indicates that the three Neoplagioporus species in the Naka River have different host range and the new species is principally infective to *C. pollux*.

**Acknowledgements.** We are grateful to Professor T. Shimazu, Nagano Prefectural College, for his kind comments on the draft.
